

1 Conditional Statements

Learning Objectives

After this section, you will be able to:

- Use a simple conditional statement in programming.
- Understand Boolean values.
- Express conditionals using comparison operators.

Conditional statements allow parts of a program to run only when certain conditions are met.

```
age = int(input("How old are you? "))

if age > 17:
    print("You are of age!")
    print("Here's a copy of GTA6 for you.")

print("Next customer, please!")
```

How old are you? 18 You are of age! Here's a copy of GTA6 for you. Next customer, please!

Comparison Operators

Common comparison operators:

Operator	Purpose	Example
==	Equal to	a == b
!=	Not equal to	a != b
>	Greater than	a > b
>=	Greater than or equal to	a >= b
<	Less than	a < b
<=	Less than or equal to	a <= b

Using if, elif, else

```
number = int(input("Please type in a number: "))

if number < 0:
    print("The number is negative.")
elif number > 0:
    print("The number is positive.")
else:
    print("The number is zero.")
```

Please type in a number: 15 The number is positive.
Please type in a number: -18 The number is negative.
Please type in a number: 0 The number is zero.

Explanation

- `if` is checked first.
- If `if` is false, `elif` is checked.
- If all previous conditions are false, `else` runs.
- Only one block executes.
